POINCARÉ DUALITY ALGEBRAS

- Let A be a graded, graded-commutative algebra over a field \mathbb{k} .
 - $A = \bigoplus_{i \geq 0} A^i$, where A^i are \mathbb{k} -vector spaces.
 - $\therefore A^i \otimes A^j \rightarrow A^{i+j}$.
 - $ab = (-1)^{ij}ba$ for all $a \in A^i, b \in B^j$.
- We will assume that A is connected ($A^0 = \mathbb{k} \cdot 1$), and locally finite (all the Betti numbers $b_i(A) := \dim_{\mathbb{k}} A^i$ are finite).
- A is a *Poincaré duality \mathbb{k} -algebra* of dimension n if there is a \mathbb{k} -linear map $\varepsilon: A^n \rightarrow \mathbb{k}$ (called an *orientation*) such that all the bilinear forms $A^i \otimes_{\mathbb{k}} A^{n-i} \rightarrow \mathbb{k}, a \otimes b \mapsto \varepsilon(ab)$ are non-singular.
- Consequently,
 - $b_i(A) = b_{n-i}(A)$, and $A^i = 0$ for $i > n$.
 - ε is an isomorphism.
 - The maps $\text{PD}: A^i \rightarrow (A^{n-i})^*, \text{PD}(a)(b) = \varepsilon(ab)$ are isomorphisms.
 - Each $a \in A^i$ has a *Poincaré dual*, $a^\vee \in A^{n-i}$, such that $\varepsilon(aa^\vee) = 1$.
 - The *orientation class* is defined as $\omega_A = 1^\vee$, so that $\varepsilon(\omega_A) = 1$.

THE ASSOCIATED ALTERNATING FORM

- Associated to a \mathbb{k} -PD $_n$ algebra there is an alternating n -form,

$$\mu_A: \bigwedge^n A^1 \rightarrow \mathbb{k}, \quad \mu_A(\mathbf{a}_1 \wedge \cdots \wedge \mathbf{a}_n) = \varepsilon(\mathbf{a}_1 \cdots \mathbf{a}_n).$$

- Assume now that $n = 3$, and set $r = b_1(A)$. Fix a basis $\{\mathbf{e}_1, \dots, \mathbf{e}_r\}$ for A^1 , and let $\{\mathbf{e}_1^\vee, \dots, \mathbf{e}_r^\vee\}$ be the dual basis for A^2 .
- The multiplication in A , then, is given on basis elements by

$$\mathbf{e}_i \mathbf{e}_j = \sum_{k=1}^r \mu_{ijk} \mathbf{e}_k^\vee, \quad \mathbf{e}_i \mathbf{e}_j^\vee = \delta_{ij} \omega,$$

where $\mu_{ijk} = \mu(\mathbf{e}_i \wedge \mathbf{e}_j \wedge \mathbf{e}_k)$.

- Alternatively, let $A_i = (A^i)^*$, and let $\mathbf{e}^i \in A_1$ be the (Kronecker) dual of \mathbf{e}_i . We may then view μ dually as a trivector,

$$\mu = \sum \mu_{ijk} \mathbf{e}^i \wedge \mathbf{e}^j \wedge \mathbf{e}^k \in \bigwedge^3 A_1,$$

which encodes the algebra structure of A .

POINCARÉ DUALITY IN ORIENTABLE MANIFOLDS

- If M is a compact, connected, orientable, n -dimensional manifold, then the cohomology ring $A = H^*(M, \mathbb{k})$ is a PD_n algebra over \mathbb{k} .
- Sullivan (1975): for every finite-dimensional \mathbb{Q} -vector space V and every alternating 3-form $\mu \in \wedge^3 V^*$, there is a closed 3-manifold M with $H^1(M, \mathbb{Q}) = V$ and cup-product form $\mu_M = \mu$.
- Such a 3-manifold can be constructed via “Borromean surgery.”

- If M bounds an oriented 4-manifold W such that the cup-product pairing on $H^2(W, M)$ is non-degenerate (e.g., if M is the link of an isolated surface singularity), then $\mu_M = 0$.

DUALITY SPACES

A more general notion of duality is due to Bieri and Eckmann (1978).

Let X be a connected, finite-type CW-complex, and set $\pi = \pi_1(X, x_0)$.

- X is a *duality space* of dimension n if $H^i(X, \mathbb{Z}\pi) = 0$ for $i \neq n$ and $H^n(X, \mathbb{Z}\pi) \neq 0$ and torsion-free.
- Let $D = H^n(X, \mathbb{Z}\pi)$ be the dualizing $\mathbb{Z}\pi$ -module. Given any $\mathbb{Z}\pi$ -module A , we have $H^i(X, A) \cong H_{n-i}(X, D \otimes A)$.
- If $D = \mathbb{Z}$, with trivial $\mathbb{Z}\pi$ -action, then X is a Poincaré duality space.
- If $X = K(\pi, 1)$ is a duality space, then π is a *duality group*.

ABELIAN DUALITY SPACES

We introduce in [Denham–S.–Yuzvinsky 2016/17] an analogous notion, by replacing $\pi \rightsquigarrow \pi_{\text{ab}}$.

- X is an *abelian duality space* of dimension n if $H^i(X, \mathbb{Z}\pi_{\text{ab}}) = 0$ for $i \neq n$ and $H^n(X, \mathbb{Z}\pi_{\text{ab}}) \neq 0$ and torsion-free.
- Let $B = H^n(X, \mathbb{Z}\pi_{\text{ab}})$ be the dualizing $\mathbb{Z}\pi_{\text{ab}}$ -module. Given any $\mathbb{Z}\pi_{\text{ab}}$ -module A , we have $H^i(X, A) \cong H_{n-i}(X, B \otimes A)$.
- The two notions of duality are independent:

EXAMPLE

- Surface groups of genus at least 2 are not abelian duality groups, though they are (Poincaré) duality groups.
- Let $\pi = \mathbb{Z}^2 * G$, where

$$G = \langle x_1, \dots, x_4 \mid x_1^{-2}x_2x_1x_2^{-1}, \dots, x_4^{-2}x_1x_4x_1^{-1} \rangle$$
 is Higman's acyclic group. Then π is an abelian duality group (of dimension 2), but not a duality group.

THEOREM (DSY)

Let X be an abelian duality space of dimension n . Then:

- $b_1(X) \geq n - 1$.
- $b_i(X) \neq 0$, for $0 \leq i \leq n$ and $b_i(X) = 0$ for $i > n$.
- $(-1)^n \chi(X) \geq 0$.

THEOREM (DENHAM–S. 2017)

Let U be a connected, smooth, complex quasi-projective variety of dimension n . Suppose U has a smooth compactification Y for which

- ① Components of $Y \setminus U$ form an arrangement of hypersurfaces \mathcal{A} ;
- ② For each submanifold X in the intersection poset $L(\mathcal{A})$, the complement of the restriction of \mathcal{A} to X is a Stein manifold.

Then U is both a duality space and an abelian duality space of dimension n .

LINEAR, ELLIPTIC, AND TORIC ARRANGEMENTS

THEOREM (DS17)

Suppose that \mathcal{A} is one of the following:

- ① An affine-linear arrangement in \mathbb{C}^n , or a hyperplane arrangement in $\mathbb{C}\mathbb{P}^n$;
- ② A non-empty elliptic arrangement in E^n ;
- ③ A toric arrangement in $(\mathbb{C}^*)^n$.

Then the complement $M(\mathcal{A})$ is both a duality space and an abelian duality space of dimension $n - r$, $n + r$, and n , respectively, where r is the corank of the arrangement.

This theorem extends several previous results:

- ① Davis, Januszkiewicz, Leary, and Okun (2011);
- ② Levin and Varchenko (2012);
- ③ Davis and Settepanella (2013), Esterov and Takeuchi (2014).

COMMUTATIVE DIFFERENTIAL GRADED ALGEBRAS

- Let $A = (A^\bullet, d)$ be a commutative, differential graded algebra over a field \mathbb{k} of characteristic 0. That is:
 - $A = \bigoplus_{i \geq 0} A^i$, where A^i are \mathbb{k} -vector spaces.
 - The multiplication $\cdot : A^i \otimes A^j \rightarrow A^{i+j}$ is graded-commutative, i.e., $ab = (-1)^{|a||b|}ba$ for all homogeneous a and b .
 - The differential $d : A^i \rightarrow A^{i+1}$ satisfies the graded Leibnitz rule, i.e., $d(ab) = d(a)b + (-1)^{|a|}ad(b)$.
- A CDGA A is of *finite-type* (or *q-finite*) if it is connected (i.e., $A^0 = \mathbb{k} \cdot 1$) and $\dim A^i < \infty$ for all $i \leq q$.
- $H^\bullet(A)$ inherits an algebra structure from A .
- A cdga morphism $\varphi : A \rightarrow B$ is both an algebra map and a cochain map. Hence, it induces a morphism $\varphi^* : H^\bullet(A) \rightarrow H^\bullet(B)$.

- A map $\varphi: A \rightarrow B$ is a *quasi-isomorphism* if φ^* is an isomorphism. Likewise, φ is a q -quasi-isomorphism (for some $q \geq 1$) if φ^* is an isomorphism in degrees $\leq q$ and is injective in degree $q + 1$.
- Two cdgas, A and B , are (q) -equivalent (\simeq_q) if there is a zig-zag of (q) -quasi-isomorphisms connecting A to B .
- A cdga A is *formal* (or just q -formal) if it is (q) -equivalent to $(H^\bullet(A), d = 0)$.
- A CDGA is q -minimal if it is of the form $(\bigwedge V, d)$, where the differential structure is the inductive limit of a sequence of Hirsch extensions of increasing degrees, and $V^i = 0$ for $i > q$.
- Every CDGA A with $H^0(A) = \mathbb{k}$ admits a q -minimal model, $\mathcal{M}_q(A)$ (i.e., a q -equivalence $\mathcal{M}_q(A) \rightarrow A$ with $\mathcal{M}_q(A) = (\bigwedge V, d)$ a q -minimal cdga), unique up to iso.

ALGEBRAIC MODELS FOR SPACES

- Given any (path-connected) space X , there is an associated Sullivan \mathbb{Q} -cdga, $A_{\text{PL}}(X)$, such that $H^\bullet(A_{\text{PL}}(X)) = H^\bullet(X, \mathbb{Q})$.
- An *algebraic (q-)model* (over \mathbb{k}) for X is a \mathbb{k} -cgda (A, d) which is (q-) equivalent to $A_{\text{PL}}(X) \otimes_{\mathbb{Q}} \mathbb{k}$.
- If M is a smooth manifold, then $\Omega_{\text{dR}}(M)$ is a model for M (over \mathbb{R}).
- Examples of spaces having finite-type models include:
 - Formal spaces (such as compact Kähler manifolds, hyperplane arrangement complements, toric spaces, etc).
 - Smooth quasi-projective varieties, compact solvmanifolds, Sasakian manifolds, etc.

RESONANCE VARIETIES OF A CDGA

- Let $A = (A^\bullet, d)$ be a connected, finite-type CDGA over $\mathbb{k} = \mathbb{C}$.
- For each $a \in Z^1(A) \cong H^1(A)$, we have a cochain complex,

$$(A^\bullet, \delta_a): A^0 \xrightarrow{\delta_a^0} A^1 \xrightarrow{\delta_a^1} A^2 \xrightarrow{\delta_a^2} \dots,$$

with differentials $\delta_a^i(u) = a \cdot u + d u$, for all $u \in A^i$.

- The *resonance varieties* of A are the affine varieties

$$\mathcal{R}_s^i(A) = \{a \in H^1(A) \mid \dim H^i(A^\bullet, \delta_a) \geq s\}.$$

- If A is a CGA (that is, $d = 0$), the resonance varieties $\mathcal{R}_s^i(A)$ are *homogeneous* subvarieties of A^1 .
- If X is a connected, finite-type CW-complex, we set $\mathcal{R}_s^i(X) := \mathcal{R}_s^i(H^\bullet(X, \mathbb{C}))$.

- Fix a \mathbb{k} -basis $\{e_1, \dots, e_r\}$ for A^1 , and let $\{x_1, \dots, x_r\}$ be the dual basis for $A_1 = (A^1)^*$.
- Identify $\text{Sym}(A_1)$ with $S = \mathbb{k}[x_1, \dots, x_r]$, the coordinate ring of the affine space A^1 .
- Define a cochain complex of free S -modules, $\mathbf{L}(A) := (A^\bullet \otimes S, \delta)$,

$$\dots \longrightarrow A^i \otimes S \xrightarrow{\delta^i} A^{i+1} \otimes S \xrightarrow{\delta^{i+1}} A^{i+2} \otimes S \longrightarrow \dots,$$

where $\delta^i(u \otimes f) = \sum_{j=1}^n e_j u \otimes f x_j + d u \otimes f$.

- The specialization of $(A \otimes S, \delta)$ at $a \in A^1$ coincides with (A, δ_a) .
- Hence, $\mathcal{R}_s^i(A)$ is the zero-set of the ideal generated by all minors of size $b_j - s + 1$ of the block-matrix $\delta^{i+1} \oplus \delta^i$.
- In particular, $\mathcal{R}_s^1(A) = V(I_{r-s}(\delta^1))$, the zero-set of the ideal of codimension s minors of δ^1 .

RESONANCE VARIETIES OF PD-ALGEBRAS

- Let A be a PD_n algebra.
- For all $0 \leq i \leq n$ and all $a \in A^1$, the square

$$\begin{array}{ccc}
 (A^{n-i})^* & \xrightarrow{(\delta_a^{n-i-1})^*} & (A^{n-i-1})^* \\
 \text{PD} \uparrow \cong & & \text{PD} \uparrow \cong \\
 A^i & \xrightarrow{\delta_a^i} & A^{i+1}
 \end{array}$$

commutes up to a sign of $(-1)^i$.

- Consequently,

$$\left(H^i(A, \delta_a) \right)^* \cong H^{n-i}(A, \delta_{-a}).$$

- Hence, for all i and s ,

$$\mathcal{R}_s^i(A) = \mathcal{R}_s^{n-i}(A).$$

- In particular, $\mathcal{R}_1^n(A) = \{0\}$.

3-DIMENSIONAL POINCARÉ DUALITY ALGEBRAS

- Let A be a PD_3 -algebra with $b_1(A) = r > 0$. Then
 - $\mathcal{R}_1^3(A) = \mathcal{R}_1^0(A) = \{0\}$.
 - $\mathcal{R}_s^2(A) = \mathcal{R}_s^1(A)$ for $1 \leq s \leq r$.
 - $\mathcal{R}_s^i(A) = \emptyset$, otherwise.
- Write $\mathcal{R}_s(A) = \mathcal{R}_s^1(A)$. Then
 - $\mathcal{R}_{2k}(A) = \mathcal{R}_{2k+1}(A)$ if r is even.
 - $\mathcal{R}_{2k-1}(A) = \mathcal{R}_{2k}(A)$ if r is odd.
- If μ_A has rank $r \geq 3$, then $\mathcal{R}_{r-2}(A) = \mathcal{R}_{r-1}(A) = \mathcal{R}_r(A) = \{0\}$.
- If $r \geq 4$, then $\dim \mathcal{R}_1(A) \geq \text{null}(\mu_A) \geq 2$.
 - Here, the *rank* of a form $\mu: \bigwedge^3 V \rightarrow \mathbb{k}$ is the minimum dimension of a linear subspace $W \subset V$ such that μ factors through $\bigwedge^3 W$.
 - The *nullity* of μ is the maximum dimension of a subspace $U \subset V$ such that $\mu(a \wedge b \wedge c) = 0$ for all $a, b \in U$ and $c \in V$.

- If r is even, then $\mathcal{R}_1(A) = \mathcal{R}_0(A) = A^1$.
- If r is odd > 1 , then $\mathcal{R}_1(A) \neq A^1$ if and only if μ_A is “generic,” that is, there is a $c \in A^1$ such that the 2-form $\gamma_c \in \bigwedge^2 A_1$ given by $\gamma_c(a \wedge b) = \mu_A(a \wedge b \wedge c)$ has rank $2g$, i.e., $\gamma_c^g \neq 0$ in $\bigwedge^{2g} A_1$.
- In that case, $\mathcal{R}_1(A)$ is the hypersurface $\text{Pf}(\mu_A) = 0$, where $\text{pf}(\delta^1(i; i)) = (-1)^{i+1} x_i \text{Pf}(\mu_A)$.

EXAMPLE

Let $M = S^1 \times \Sigma_g$, where $g \geq 2$. Then $\mu_M = \sum_{i=1}^g a_i b_i c$ is generic, and $\text{Pf}(\mu_M) = x_{2g+1}^{g-1}$. Hence, $\mathcal{R}_1 = \cdots = \mathcal{R}_{2g-2} = \{x_{2g+1} = 0\}$ and $\mathcal{R}_{2g-1} = \mathcal{R}_{2g} = \mathcal{R}_{2g+1} = \{0\}$.

PROPAGATION OF RESONANCE

- We say that the resonance varieties of a graded algebra $A = \bigoplus_{i=0}^n A^i$ propagate if $\mathcal{R}_1^1(A) \subseteq \cdots \subseteq \mathcal{R}_1^n(A)$.
- (Eisenbud–Popescu–Yuzvinsky 2003) If X is the complement of a hyperplane arrangement, then its resonance varieties propagate.

THEOREM (DSY 2016/17)

- Suppose the \mathbb{k} -dual of A has a linear free resolution over $E = \bigwedge A^1$. Then the resonance varieties of A propagate.
- Let X be a formal, abelian duality space. Then the resonance varieties of X propagate.
- Let M be a closed, orientable 3-manifold. If $b_1(M)$ is even and non-zero, then the resonance varieties of M do not propagate.

CHARACTERISTIC VARIETIES

- Let X be a connected, finite-type CW-complex. Then $\pi = \pi_1(X, x_0)$ is a finitely presented group, with $\pi_{\text{ab}} \cong H_1(X, \mathbb{Z})$.
- The ring $R = \mathbb{C}[\pi_{\text{ab}}]$ is the coordinate ring of the character group, $\text{Char}(X) = \text{Hom}(\pi, \mathbb{C}^*) \cong (\mathbb{C}^*)^r \times \text{Tors}(\pi_{\text{ab}})$, where $r = b_1(X)$.
- The *characteristic varieties* of X are the homology jump loci

$$\mathcal{V}_s^i(X) = \{\rho \in \text{Char}(X) \mid \dim H_i(X, \mathbb{C}_\rho) \geq s\}.$$

- These varieties are homotopy-type invariants of X , with $\mathcal{V}_s^1(X)$ depending only on $\pi = \pi_1(X)$.
- Set $\mathcal{V}_1(\pi) := \mathcal{V}_1^1(K(\pi, 1))$; then $\mathcal{V}_1(\pi) = \mathcal{V}_1(\pi/\pi'')$.

EXAMPLE

Let $f \in \mathbb{Z}[t_1^{\pm 1}, \dots, t_n^{\pm 1}]$ be a Laurent polynomial, $f(1) = 0$. There is then a finitely presented group π with $\pi_{\text{ab}} = \mathbb{Z}^n$ such that $\mathcal{V}_1(\pi) = \mathbf{V}(f)$.

THEOREM (DSY)

Let X be an abelian duality space of dimension n . If $\rho: \pi_1(X) \rightarrow \mathbb{C}^*$ satisfies $H^i(X, \mathbb{C}_\rho) \neq 0$, then $H^j(X, \mathbb{C}_\rho) \neq 0$, for all $i \leq j \leq n$.

COROLLARY

Let X be an abelian duality space of dimension n . Then The characteristic varieties propagate, i.e., $\mathcal{V}_1^1(X) \subseteq \dots \subseteq \mathcal{V}_1^n(X)$.

INFINITESIMAL FINITENESS OBSTRUCTIONS

QUESTION

Let X be a connected CW-complex with finite q -skeleton. Does X admit a q -finite q -model A ?

THEOREM

If X is as above, then, for all $i \leq q$ and all s :

- (Dimca–Papadima 2014) $\mathcal{V}_s^i(X)_{(1)} \cong \mathcal{R}_s^i(A)_{(0)}$.
In particular, if X is q -formal, then $\mathcal{V}_s^i(X)_{(1)} \cong \mathcal{R}_s^i(X)_{(0)}$.
- (Macinic, Papadima, Popescu, S. 2017) $\mathrm{TC}_0(\mathcal{R}_s^i(A)) \subseteq \mathcal{R}_s^i(X)$.
- (Budur–Wang 2017) All the irreducible components of $\mathcal{V}^i(X)$ passing through the origin of $H^1(X, \mathbb{C}^*)$ are algebraic subtori.

EXAMPLE

Let π be a finitely presented group with $\pi_{\mathrm{ab}} = \mathbb{Z}^n$ and $\mathcal{V}_1(\pi) = \{t \in (\mathbb{C}^*)^n \mid \sum_{i=1}^n t_i = n\}$. Then π admits no 1-finite 1-model.

THEOREM (PAPADIMA–S. 2017)

Suppose X is $(q+1)$ finite, or X admits a q -finite q -model. Then $b_i(\mathcal{M}_q(X)) < \infty$, for all $i \leq q+1$.

COROLLARY

Let π be a finitely generated group. Assume that either π is finitely presented, or π has a 1-finite 1-model. Then $b_2(\mathcal{M}_1(\pi)) < \infty$.

EXAMPLE

- Consider the free metabelian group $\pi = F_n / F_n''$ with $n \geq 2$.
- We have $\mathcal{V}_1(\pi) = \mathcal{V}_1(F_n) = (\mathbb{C}^*)^n$, and so π passes the Budur–Wang test.
- But $b_2(\mathcal{M}_1(\pi)) = \infty$, and so π admits no 1-finite 1-model (and is not finitely presented).

A TANGENT CONE THEOREM FOR 3-MANIFOLDS

THEOREM

Let M be a closed, orientable, 3-dimensional manifold. Suppose $b_1(M)$ is odd and μ_M is generic. Then $\text{TC}_1(\mathcal{V}_1^1(M)) = \mathcal{R}_1^1(M)$.

- If $b_1(M)$ is even, the conclusion may or may not hold:
 - Let $M = S^1 \times S^2 \# S^1 \times S^2$; then $\mathcal{V}_1^1(M) = \text{Char}(M) = (\mathbb{C}^*)^2$, and so $\text{TC}_1(\mathcal{V}_1^1(M)) = \mathcal{R}_1^1(M) = \mathbb{C}^2$.
 - Let M be the Heisenberg nilmanifold; then $\text{TC}_1(\mathcal{V}_1^1(M)) = \{0\}$, whereas $\mathcal{R}_1^1(M) = \mathbb{C}^2$.
- Let M be a closed, orientable 3-manifold with $b_1 = 7$ and $\mu = e_1 e_3 e_5 + e_1 e_4 e_7 + e_2 e_5 e_7 + e_3 e_6 e_7 + e_4 e_5 e_6$. Then μ is generic and $\text{Pf}(\mu) = (x_5^2 + x_7^2)^2$. Hence, $\mathcal{R}_1^1(M) = \{x_5^2 + x_7^2 = 0\}$ splits as a union of two hyperplanes over \mathbb{C} , but not over \mathbb{Q} .
